## Abstract

Improving the energy performance of existing buildings is crucial for reaching both EU and national climate and energy targets. The main objective of this study was to map challenges that owners of Swedish multi-family houses perceive when making energy-efficiency refurbishments. A secondary objective was to compare how well the challenges reported by the housing owners relate to national strategies proposed by the Swedish National Board of Housing, Building and Planning and the Swedish Energy Agency. The study applied a combined methods approach with audience response meters and in-depth qualitative semi-structured interviews. The housing owners express the view that they have sufficient knowledge of national ambitions to improve the energy performance of buildings and welcome the new building regulations. Despite this supposed knowledge and the current economic situation with beneficial loans, the refurbishment rate still remains low. The housing owners explain that they are waiting for proof that all sustainability goals can be reached in refurbishment projects in reality. A crucial aspect is to address the “performance gap”. In order to make more accurate energy performance predictions the actual energy performance of renovated buildings have to be monitored. Probably, too few projects fulfilling ambitions in all categories: economically, socially and energy-wise have been followed up and demonstrated nationally. The new national information centre about refurbishment of buildings may help to spread information about such projects, raise awareness and thus increase the refurbishment rate.

## 1 Introduction

The EU has, through the Energy Performance of Buildings Directive (EPBD) (2010/31/EU and 2012/27/EU), established goals for reducing overall primary energy consumption, reducing CO<sub>2</sub> emissions, and increasing the share of renewable energy in the building sector [1]. There is a huge potential for energy savings in existing buildings. It has been recognized that improving the performance of existing buildings is crucial for reaching both EU and national climate and energy targets, moving towards a more sustainable energy system. Often, it is possible to cut energy consumption in half, and in many cases the modifications are economically beneficial for the real estate owner from a building life cycle perspective. [2, 3].

It is up to each country to create their own incitements in order to reach these goals. According to implementation of the Energy Efficiency Directive (2012/27/EU): Energy Efficiency Obligation Schemes [4], there are totally 479 policy measures implemented or planned to implement; the largest share of the overall savings is expected from energy efficiency obligation schemes (34%), financing schemes or grants (19%), and from taxes (14%). Some countries launched very few policy instruments (e.g. Italy) whereas others such as Germany or Slovakia adopted 112 and 66 policy instruments respectively. Among these policies [5-8]. France has mandated renovation for commercial buildings, requiring individual buildings to develop a “plan for renovation” that will result in reduction of energy consumption by at least 25% relative to the 2010 performance level; Netherlands published grant scheme for landlords to improve insulation in rented properties and energy labels for housing; the UK government also introduced the Green Deal framework, to make the “Pay as You Save” system for home energy efficiency more accessible to businesses, while ensuring adequate protection for consumers; in California USA, financial incentives for energy efficiency measures are funded via the Public Goods Charge levied on the electricity and gas prices; the Italian government allows homeowners to deduct up to 55% of the expenses incurred to implement energy efficiency renovations or renewable energy

1  
2  
3 technologies in existing homes from their income tax. The focus of the Swedish National Board  
4  
5 of Housing, Building and Planning (SNBHBP) has historically been to set up building regulations  
6  
7 for new buildings [9]. However, existing buildings undergoing major modifications should,  
8  
9 according to the regulations, be modified to reach the same energy performance levels as new  
10  
11 buildings, if possible. In practice, the regulations related to the modification of existing building  
12  
13 have been difficult to control and follow up.

14  
15  
16 Back in 2013, SNBHBP and the Swedish Energy Agency suggested the first national strategy for  
17  
18 the energy efficiency refurbishment of buildings [10]. This was carried out after directions from  
19  
20 the Swedish government, in accordance with the EU Energy Efficiency Directive. The report  
21  
22 shows three cases; a reference case with current policy instruments in effect until 2050, one case  
23  
24 (scenario 1) with additional informative policy instruments and one case (scenario 2) exploring  
25  
26 what is required to reach a 50 % reduction of purchased energy use in buildings. The results  
27  
28 show that the reference case will reach a 22-30 % reduction in purchased energy by 2050 (as  
29  
30 compared to 1995). Scenario 1 will reach a 26-40 % reduction with suggested informative policy  
31  
32 instruments including a renovation center working with energy efficiency and refurbishment as  
33  
34 well as more information regarding energy efficiency measures to banks, in order to give them a  
35  
36 better understanding of the economic potential and thereby provide more favorable loans. In  
37  
38 order to reach a 50 % reduction in purchased energy (scenario 2), working with additional policy  
39  
40 instruments alone is not enough, according to SNBHBP. Instead, the renovation rate needs to  
41  
42 increase significantly in order to reach this goal. However, the scope of SNBHBP's first study did  
43  
44 not include this aspect.

45  
46  
47  
48  
49 The national refurbishment strategy was further expanded in 2015 [11]. Two main obstacles for  
50  
51 the energy efficiency refurbishments mentioned are housing owners' lack of knowledge and  
52  
53 financial difficulty. More detailed suggestions for the set-up of an information centre for  
54  
55 refurbishment are proposed. An information centre should help owners of multi-family houses to  
56  
57

1  
2  
3 acquire the knowledge necessary to make well-informed decisions with regard to energy  
4 efficiency refurbishments. Regarding financial issues, three obstacles are mentioned. The first  
5 obstacle is that housing owners do not have enough equity to undertake energy-efficient  
6 refurbishments without taking large loans. The second obstacle, which is linked to the first one, is  
7 the high costs for loans, and the third obstacle is the problem of not generating enough extra  
8 revenue after the refurbishments to make them profitable. The third obstacle is partly due to how  
9 apartment rent is regulated, with limitations on how much the rent can be increased after  
10 refurbishment, and this partly reconnects back to a lack of knowledge, with housing owners  
11 being unable to identify profitable energy efficiency refurbishment measures. These will all lead  
12 to profitable energy efficiency refurbishments not being explored fully, with unnecessarily high  
13 energy use after refurbishment as a consequence. Regarding financial difficulties, the report  
14 suggests that the state credit guarantee should be expanded to include refurbishments as well, in  
15 order to increase the rate of refurbishment.

29  
30

31 In November 2016, SNBHBP and the Swedish Energy Agency came with even more updates of  
32 the national strategy for the energy efficiency refurbishment of buildings, in order to stimulate an  
33 increased refurbishment rate [12]. In the report, it was concluded that the main challenges  
34 housing owners face are related to high expenses in the building sector at the moment. The great  
35 need for new dwellings increases building costs and limits the opportunities to upgrade the  
36 existing building stock. Increased competition among entrepreneurs and new technologies are  
37 needed to reduce costs, according to the report.

43  
44  
45  
46

47 Recently, SNBHBP has released revised national energy directives for new and existing buildings,  
48 called “near zero energy building regulations” (NNE) [13]. The new regulations do not call for  
49 improved energy performance compared to the previous building regulations (BBR 24), just  
50 change the way of calculating performance based on primary energy factors. The paragraphs  
51 regarding the modification of existing buildings have not changed.

3 As long as five years ago, major players in the building sector and academia with a base at Lund  
4 University, created “Renoveringscentrum”, a centre partly funded by research money [14]. The  
5 purpose of this centre was, just like the intended national information centre, to spread  
6 information and knowledge about energy-efficient and sustainable refurbishment. Not before  
7 2017 the government decided to give “Renoveringscentrum” and “Svensk Byggtjänst” ”, a public  
8 limited company, the responsibility and financial support to establish a national information  
9 centre, called “Nationellt Renoveringscentrum” (NRC), based on the existing center. Together a  
10 web page with information about the refurbishment of buildings was created to reach all actors in  
11 the building sector [15].

22

23 Regardless of the building regulations, information center and financial incentives being realized  
24 as anticipated or not, the renovation of existing multi-family houses is still not making substantial  
25 progress. The progress to a national information center might help, but the reasons why owners  
26 of multi-family houses still hesitate to start energy-efficient refurbishments are still unclear.  
27

30  
31

### 32 **1.1 Scope and objectives**

33  
34  
35 The main objective of this study was to map the perceived challenges that owners of Swedish  
36 multi-family houses see from their own perspective regarding energy efficiency refurbishments.  
37 On purpose, the study was based open questions and open discussion to allow attendees to  
38 express their understanding why the energy efficiency refurbishments rate remain low in Sweden.  
39  
40  
41  
42  
43

44  
45 A secondary objective was to compare how well the challenges reported by the house owners  
46 relate to the challenges identified and strategies proposed by SNBHBP and the Swedish Energy  
47 Agency in report ET 2013:22 and Boverket 2015:47 [10-11].

1  
2  
3 Energy companies were consulted to get their view on the energy efficiency refurbishment of  
4 buildings. The underlying goal of the study was to identify ways to assist and stimulate owners of  
5 multi-family houses to increase the rate of energy-efficient refurbishment projects.  
6  
7

8  
9  
10 The study was conducted in a Swedish context and was carried out as a part of the research  
11 project: Gentle Energy-Efficient Refurbishment, funded by the Swedish Energy Agency program  
12 “E2B2” [16]. In the project, a local municipal housing owners and Dalarna University collaborate  
13 in the refurbishment of a demonstration building, called a “Living Lab” reported within the  
14 “Sustainable Integrated Renovation” network [17]. The aim is a general improvement of energy  
15 performance with added energy efficiency measures for ecological sustainability and lower energy  
16 costs. The details of the project are reported in the Swedish Energy Agency program “E2B2”  
17 [18].

24  
25  
26  
27

28 ByggDialog Dalarna, a network of companies from the building sector in the region of Dalarna, a  
29 county in Sweden, organize seminars and workshops to spread information and results from  
30 projects such as Gentle Energy-Efficient Refurbishment. ByggDialog Dalarna has also proposed  
31 a local strategy for energy-efficient refurbishment, called “Strategy for Low Energy Buildings in  
32 Dalarna” (in Swedish) [19]. Data for this study were obtained at some of ByggDialog Dalarna’s  
33 workshops, as relevant information was displayed and discussed among regional actors in the  
34 sector. Even though housing owners contributing to the empirical material were local, the studied  
35 challenges have general interest for the national Swedish context.

## 46 **2 The potential of energy-efficient refurbishment measures and tools to support the**

### 47 **refurbishment process**

48  
49

50  
51 Energy use in buildings represents about 40% of the EU's total final energy consumption and  
52 CO<sub>2</sub> emissions – and this is the same in Sweden. The refurbishment rates are low, 1.2% per year  
53 in the EU with similar figures in Sweden, as discussed in the report “Suggestions for incitements  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 to increase the rate of refurbishments” [20]. The potential for energy savings is substantial.  
4  
5 According to an evaluation of the Energy Performance of Buildings Directive roadmap, the EU  
6  
7 needs to boost the number of major refurbishments and speed up the refurbishment rate of the  
8  
9 existing stock to above 2% annually in order to reach energy and environmental targets. [1]  
10

11  
12 A large share of the building stock in Sweden was built about 50-60 years ago, during the “million  
13  
14 programme” (a large public housing programme to construct one million dwellings for low  
15  
16 income families in urban areas), such as the building focused on in this case study. These  
17  
18 buildings are often in need of general improvement and synchronized energy improvements, and  
19  
20 are therefore particularly important to address as refurbishment objects [21]. Unlike most  
21  
22 Swedish detached houses, and European multi-family buildings which most frequently have  
23  
24 separate heating systems, 91 % of the Swedish multi-family buildings are heated by district  
25  
26 heating networks [22]. Most of these old buildings have similar building construction and simple  
27  
28 exhaust ventilation systems without heat recovery (58%) or natural ventilation (38%)[23]. The  
29  
30 average specific energy use is typically roughly 150-200 kWh/m<sup>2</sup>, year. These many similarities  
31  
32 mean that refurbishment projects on a single building, such as the building in this case study, also  
33  
34 are relevant for a large number of buildings in the entire country.  
35  
36  
37

38  
39 Various examples of major refurbishment of buildings from the “million programme” have been  
40  
41 presented nationally [14, 15, 24-26]. These typically include refurbishment measures such as  
42  
43 balanced ventilation with heat recovery, and improved insulation of the building envelope. A  
44  
45 hypothesis in the project Gentle Energy-Efficient Refurbishment is that many of these  
46  
47 refurbishment examples have been too extensive, and, as a result, the investment costs become  
48  
49 too high to be rational for most housing owners. The project “Brogården” in Alingsås is one  
50  
51 example where the refurbishment cost was about 2000 €/m<sup>2</sup> resulting in a rent rise of about 50%.  
52  
53 The energy saving was only 20 €/m<sup>2</sup> annually. [27] One drawback with this kind of renovation  
54  
55 resulting in a high rent increase is that tenants with lower income are forced to move [28].  
56  
57  
58  
59  
60

1  
2  
3 In the Gentle Energy-Efficient Refurbishment project, on the other hand, refurbishment  
4 packages spanning from “light”, with moderate energy savings, to costlier, with near zero energy  
5 standards were therefore presented as alternatives to choose from for the housing owners owner.  
6  
7 The idea was to emphasize refurbishment measures having less impact on the building and its  
8 tenants, such as: exhaust air heat pumps added to the existing ductwork, insulation to the attic,  
9 ventilation radiators to pre-heat incoming air, window improvements, solar cells, efficient water-  
10 taps, etc. A crucial question was to find out which level should be chosen to acquire an optimal  
11 balance between the degree of energy improvement in each individual building and the frequency  
12 of energy efficiency work from building to building. Of earlier projects in Sweden, Milparena in  
13 Göteborg, had a similar context with limited financial resources for energy efficiency  
14 improvements, the district heating price was low and only a moderate rent raise for tenants could  
15 be acceptable for socio-economic reasons [29].  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28

29 How frequent housing owners actually use the newly constructed national renovation center has  
30 not been documented to this date. For some time, “BEBO”, a network of housing owners  
31 supported by the Swedish Energy Agency, has been an alternative information channel regarding  
32 energy-efficient refurbishment [30]. But in reality, most of the planning and calculation of energy  
33 efficient refurbishment is outsourced to consultants. These work under strict time constraints in a  
34 rapidly expanding building sector. As this article was written, Sweden had the highest building  
35 price per square meter in the EU [31]. Due to this circumstance and the fact that modern  
36 buildings, and especially their service systems, are becoming more and more complex, there is a  
37 risk that the consultants only present one or two alternative solutions, not taking time to present  
38 any “green” or “energy-efficient” alternatives. Research studies have even shown that consultants  
39 often predict energy performance levels which are seldom reached in reality, resulting in a so  
40 called “performance gap” between predicted and actual energy performance [32, 33].  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Tools or guides may help housing owners to choose refurbishment measures and to remind them  
4  
5 to consider energy aspects continuously in all stages of a refurbishment process. Bygga E is an  
6  
7 example of such a guide written by Research Institutes of Sweden, RISE, and it communicates  
8  
9 how work with energy aspects can naturally be included in the process from planning, to  
10  
11 production, to the stage where the building is completed [34]. Sveby, a development program  
12  
13 financed by the Swedish Energy Agency together with many of the largest housing owners  
14  
15 owners in Sweden, provides similar tools used to standardize and verify energy performance in  
16  
17 buildings (handbooks, calculation tools and checklists, etc.) [35].  
18

19  
20  
21 In the Swedish building market, BREEAM SE, LEED, WELL and Miljöbyggnad are generally  
22  
23 preferred. These building certification systems set requirements regarding many categories  
24  
25 comprising energy performance and environmental aspects and Miljöbyggnad is the most  
26  
27 common system in Sweden [36]. If the housing owner demands a proposal on optional  
28  
29 refurbishment packages aiming for high certification ratings from the consultant, energy aspects  
30  
31 are easily secured in the planning process. But so far, certification of buildings from the “million  
32  
33 programme” era have been uncommon.  
34

35  
36  
37 Financial calculations for energy measures vary from simple pay-back calculations to life cycle  
38  
39 calculations (LCC) or other methods such as the Total Concept method [37]. Total Concept is a  
40  
41 method used to ensure as many refurbishment measures as possible are included in an  
42  
43 economically viable “energy refurbishment package”, i.e. one that falls within the company  
44  
45 requirement for a return on investment. What is common for all methods is that it can be  
46  
47 challenging to evaluate the economic outcome over a building’s life span due to uncertainty over  
48  
49 future energy prices, etc. Farsäter et.al claims that a standard on how to structure the  
50  
51 methodology and input data to be used when calculating economical profitability, would  
52  
53 contribute to the process of disseminating information on renovation projects [38]. In the same  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 paper a synthesis of renovation projects shows the variety of calculation methods used, but only  
4  
5 about half of investigated renovation projects were considered to be profitable.  
6  
7

8 It can also be challenging and complex to balance economic aspects with social and ecological  
9  
10 sustainability. There is, for example, a risk of increasing societal inequity due to rent increases in  
11  
12 renovated buildings, as reported by Mangold et al. [39]. Renobuild, a new commercial tool  
13  
14 developed by RISE, was developed to assist housing owners in the refurbishment process of  
15  
16 multi-family buildings. The tool takes into account the social, ecological and economic  
17  
18 consequences of refurbishment. Because it focuses solely on refurbishment, not the construction  
19  
20 of new buildings, it is more efficient in assisting the choice of refurbishment measures [40].  
21  
22

23  
24 Since the Swedish building regulations have always considered purchased energy, not primary  
25  
26 energy as in the EU directive, it has been difficult to judge the real environmental impact through  
27  
28 saving electricity compared with making savings through other energy carriers. The situation is  
29  
30 especially complex for buildings connected to a district heating network, such as most multi-  
31  
32 family buildings in Sweden. Reducing the district heating demand by a certain amount, but  
33  
34 increasing electricity demand by a lower amount, may actually lead to an increased environmental  
35  
36 impact [41, 42]. New national energy performance of building regulations based on primary  
37  
38 energy factors have only recently been introduced by SNBHBP (BBR (A), BFS 2017:5).  
39  
40

41  
42 Research papers may help in choosing a renovation strategy and making decisions on renovation  
43  
44 measures. But according to Farsäter [43] only about 5 % of 234 papers on refurbishment  
45  
46 compiled and reviewed cover all sustainability aspects (and never all three aspects in-depth). The  
47  
48 most comprehensive research work on the ecological aspects of refurbishment are being  
49  
50 conducted within the research school REESBE (Resource and Energy-Efficient Built  
51  
52 Environment) [44]. When it comes to social sustainability in refurbishment projects, important  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 studies have been collected in the anthology, Sustainable Integrated Refurbishment (in Swedish)  
4  
5 [45].  
6  
7

8 Most countries within the EU with comparable conditions, such as Denmark, are at the same  
9  
10 stage regarding investment subsidies for refurbishment, energy consultants to increase relevant  
11  
12 expertise, and mandatory energy reports [46], while Germany has reached furthest, regarding  
13  
14 regulatory instruments and subsidy programs together with communicative instruments, to  
15  
16 motivate homeowners to pursue energy-efficient refurbishment. To date, Germany has been  
17  
18 successful in some aspects, such as stimulating the implementation of solar cells, while it has  
19  
20 been more limited regarding the deep renovation of buildings. Stieß and Dunkelberg address the  
21  
22 question of how to improve or supplement German political instruments in order to increase the  
23  
24 refurbishment rates further and tap the full potential savings [47]. They analyze the existing policy  
25  
26 instruments and the barriers responsible for the discrepancy between potential and actual  
27  
28 refurbishment rates. They conclude that the rate of energy refurbishment of existing multi-family  
29  
30 buildings is very much linked with coordinated campaigns and the escalation of gas and electricity  
31  
32 prices.  
33  
34  
35

36 Few studies map how the owners of multi-family housing value their own expertise and  
37  
38 challenges in energy-efficient refurbishment, and their awareness of tools available to assist in  
39  
40 refurbishment projects like the present work. Here, data were collected both qualitative through  
41  
42 deep interviews and quantitative in interactive workshops with a larger group of representatives  
43  
44 from the building sector.  
45  
46  
47

### 48 **3 Methodology** 49

50  
51 This study applied a combined methods approach [48]. First, quantitative data were collected  
52  
53 during two workshops held by ByggDialog Dalarna. Twelve representatives from regional  
54  
55 housing attended the first workshop. Among these were the two largest local municipal housing  
56  
57  
58  
59  
60

1  
2  
3 companies in Dalarna county, owning between 60-70 % of the total number of rental apartments  
4  
5 in their respective municipalities. The range of companies, from the two largest local municipal  
6  
7 companies mentioned above, down to private medium and small-sized companies, was chosen to  
8  
9 reflect the whole span of means, terms and conditions housing owners have in order to conduct  
10  
11 energy-efficient refurbishments.

12  
13 The second workshop comprised 12 representatives of energy companies. This workshop was  
14  
15 held in order to obtain an understanding of energy companies' roles in energy-efficient  
16  
17 refurbishments. During both occasions, the research project Gentle Energy-Efficient  
18  
19 Refurbishment was presented to introduce the participants to a relevant refurbishment project.  
20  
21 The particular case study was discussed, but also energy-efficient refurbishment in general.  
22  
23 Relevant questions were then presented to the audience and responses were collected using  
24  
25 clickers or audience response meters [49]. In this way, all the participants could give a response to  
26  
27 each question anonymously and express their own perspectives. The results were displayed on a  
28  
29 screen in real time, accompanied by further discussion and questions. The response frequency  
30  
31 was always 100% as the participants were asked to vote "no opinion" as an option. Some  
32  
33 questions were directly related to the ongoing research project, while others were general for the  
34  
35 building sector, see **Table 1**.

36  
37  
38  
39 Finally, in-depth qualitative semi-structured interviews were carried out with a representative of  
40  
41 ByggDialog Dalarna, the CEO of a large municipal housing company, the technical manager of  
42  
43 another large municipal housing company, and the technical manager of a medium-sized private  
44  
45 housing company [50-52].

46  
47  
48  
49 The purpose of interviewing ByggDialog Dalarna was to apprehend the opinion of an academic  
50  
51 partner working closely with the building sector in the region. The interviews with the housing  
52  
53 owners were to provide a deeper understanding of the challenges companies perceive, both  
54  
55 municipal and private.

1  
2  
3 All interview subjects were introduced to five open general questions to allow them to reflect on  
4 the themes, freely, and in discussions during the interviews. Some specific questions were  
5 prepared for each “category”, only to make sure that the most vital aspects were covered. The  
6 interviews were taped, transcribed and abstractions, i.e. data reduction, were made from the  
7 emerging themes. The results of the interviews are presented in section 4.2.  
8  
9  
10  
11  
12

## 13 14 **4 Results**

15  
16  
17 The results from the workshops about energy efficiency work in the building sector, where 12  
18 housing owners and 12 energy companies attended, are presented in **Figure 1 and Table 1**.  
19 Related statements of importance are summarized below.  
20

39  
40

### 41 **4.1 Résumés from the workshops**

42  
43  
44 The most challenging factor in energy-efficient refurbishment is “economy”, according to the  
45 housing owners and the energy companies leaving votes with the audience response meters, see  
46 Figure 1. The current building regulations, on the other hand, was considered to be a minor  
47 hindrance on refurbishment projects. While challenges related to expertise and technological  
48 limitations were more problematized by the energy companies than the housing owners.  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 The majority (74 %) of the representatives of housing owners indicated that they have  
4 considerable or very much knowledge about national strategies to increase the rate of energy  
5 efficient refurbishment. However, the housing owners stress that they are often under time  
6 pressure, and their technicians should be more involved in the planning of energy efficiency work.  
7  
8 Very seldom projects have clear goals and proper project management to reach the goals and  
9 verification of fulfillment afterwards, according to more than half of the attendees (see Table 1).  
10  
11 Probably implementing certification systems such as BREEAM, LEED, WELL or  
12 “Miljöbyggnad” could help to involve those with in-house knowledge more time efficiently (94%  
13 of the housing companies and 62% of the energy companies indicated that these kind of tools  
14 could be of great use). However, the initial effort and costs to start certifying existing buildings  
15 from the “million programme” era seem too high, according to the discussion. On the  
16  
17 contractionary, the housing owners stress the importance of documenting/recycling knowledge  
18 from one refurbishment project to the next (100% agreement).  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

31 A debated issue during the workshop was the importance of having the right in-house knowledge  
32 among housing owners to make smart decisions in refurbishment projects. Still the housing  
33 owners and energy companies indicated with the audience response meters that the housing  
34 owners are very dependent on consultants in energy efficiency work. The housing owners  
35 explained that many believe that calculated energy performance levels seldom are reached in  
36 reality. That could be a major reason for hesitation regarding refurbishment among housing  
37 owners. These housing owners do not believe that the energy and financial savings estimated by  
38 consultants are viable. Improved interaction with the consultants could probably improve the  
39 quality of energy performance predictions, according to the discussion.  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50

51 Most attendees agreed that it is more important to lower electricity demand than heat demand.  
52  
53 Hesitation to start refurbishment projects could also be related to the old building regulations.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 The last argument to wait or only carry out cosmetic or less costly improvements, rather than  
4 expensive energy efficiency measures, was to avoid increased rent for tenants.  
5  
6

7  
8 After the Gentle energy-efficient refurbishment case had been presented [18], the housing  
9 owners discussed and nominated the most appropriate refurbishment package among a few  
10 alternatives. No one chose the most comprehensive or “deep” refurbishment package. Instead,  
11 all choose lighter, less costly, refurbishment packages. Only two voted for solar cells (technical  
12 aspects are not covered in depth in this study).  
13  
14  
15  
16  
17

18  
19 Most attendees had taken benefit from the BEBO network directly or indirectly [30], but no one  
20 knew about the new national information centre about refurbishment at the time of the work  
21 shop.  
22  
23  
24  
25

#### 26 27 **4.2 Results from the qualitative interviews**

28  
29 Below follows a summary of the themes emerging from the qualitative interviews.  
30  
31

##### 32 33 **Housing owners’ knowledge levels regarding national building regulations and future** 34 35 **energy policies** 36 37

38  
39 From the organization ByggDialog Dalarna, it was clearly stated that there is a lack of in depth  
40 knowledge among housing owners due to the supplementary training level being lower in the  
41 building sector than in most other sectors. As regards the private sector, there is even less  
42 knowledge about energy-efficient refurbishment than among the public-sector actors.  
43  
44  
45  
46

47  
48 These views were not completely embraced by the municipal company A who stated that they  
49 had in depth knowledge about national building regulations and goals. However, they also  
50 expressed the view that when starting a refurbishment of a multi-family building, as in the case of  
51 the Gentle Energy-Efficient Refurbishment: ”We have to consider our “triple bottom line”;  
52  
53  
54  
55  
56  
57

1  
2  
3 which means we try to secure sustainability in all three categories: social, ecological and  
4  
5 economical. In a previous case we lowered the energy consumption from 150 kWh/m<sup>2</sup> to less  
6  
7 than half.”

8  
9  
10 The company state, though, that the project was not socially sustainable because the tenants  
11  
12 could not afford the consequential rise in rent. Neither was it economically sustainable because  
13  
14 the need for write-offs became too high. The company, therefore, reconsidered the strategy and  
15  
16 plan to spend less money on the next refurbishment case. “This way we fulfil our “triple bottom  
17  
18 line” and we can secure a higher refurbishment rate on our building stock. Still, the ambition is to  
19  
20 cut the energy consumption to about half.”

21  
22  
23 In municipal company B, they believed that housing owners with 1000 apartments or more  
24  
25 generally have good knowledge of building rules and goals. SABO, the Swedish Association of  
26  
27 Public Housing Companies, is the most important forum to share experience and knowledge [53].  
28  
29 It is mainly the large municipal owners which attend SABO or BEBO meetings. The company  
30  
31 also thought that there has been a mismatch between EU directives and the national building  
32  
33 regulations, which have made energy-efficient refurbishment problematic. “With the old Swedish  
34  
35 regulations (BBR 24) there was risk for unwise decisions because the goals are set in purchased  
36  
37 energy even if we talk about environmental aspects. It’s not necessarily better to aim for a  
38  
39 purchased energy level of 50 kWh/m<sup>2</sup> instead of 80 kWh/m<sup>2</sup>. We need to have better life cycle  
40  
41 and energy system perspectives. Building rules should be set in primary energy or CO<sub>2</sub> per square  
42  
43 meter, not purchased energy. The new regulations (BBR 25) is a step in the right direction”.

44  
45  
46  
47  
48 In the private company, they concluded that there was in-house competence because they were  
49  
50 affiliated to a company working with building construction. They also believed that in small  
51  
52 private housing owners, knowledge is often dependent on interest among individuals. “But since  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 we are a relatively large company, we monitor our energy consumption and have our own energy  
4 targets”.

5  
6  
7  
8 **Housing owners' reasons for starting refurbishment of existing multi-family buildings**  
9  
10 **and the importance of energy efficiency**

11  
12  
13 According to ByggDialog Dalarna, the main reasons for refurbishment and improvement are the  
14 bad condition of buildings and “unhappy tenants”. The energy cost is not considered to be a  
15 ruling factor, although energy aspects are sometimes included through energy performance  
16 contracting (EPC).  
17  
18  
19  
20  
21

22  
23 For municipal company A, the main reason to refurbish is to prolong the lifespan of “million  
24 programme” buildings in order to avoid value loss. A second important aspect of refurbishing  
25 that company A brings up is the improvement of the indoor climate, which connects back to  
26 ByggDialog Dalarna’s mention of “unhappy tenants”. In order to learn more regarding the  
27 energy aspects of refurbishing, the company has also initiated collaboration projects with  
28 academia.  
29  
30  
31  
32  
33  
34  
35

36  
37 Municipal company B also showed similar priorities, with an extension of building life being the  
38 main factor for refurbishing. Maintaining satisfactory living standards for tenants was also  
39 brought forward as an important aspect. Regarding energy efficiency, company B stated they  
40 never carry out costly “deep refurbishment” and that energy aspects are timed with bathroom  
41 and drainage pipe renovations.  
42  
43  
44  
45  
46  
47

48  
49 The private company simply stated that refurbishment is initiated when a building is in need of  
50 maintenance. As for energy efficiency measures, they are, according to the private company, only  
51 economically feasible when timed with general maintenance.  
52  
53  
54

55  
56 **Main challenges when carrying out energy efficiency work**  
57

1  
2  
3 Economic factors provide the main challenges, followed by technical barriers, according to  
4 ByggDialog Dalarna. They also see that housing owners often lack technical expertise, leading to  
5 difficulties in making the right decisions. Historically, the housing owners would often reason  
6 with potential entrepreneurs about possible refurbishment measures in the initial stage of a  
7 refurbishment process. Over the last few years, a strict legal tendering process might frighten  
8 housing owners from contacting entrepreneurs at an early stage so as not to give anyone an  
9 advantage. However, times are changing fast and the hot building sector again inspires dialog and  
10 forms of partnering.  
11  
12

13  
14  
15  
16  
17  
18  
19  
20  
21 Municipal company A also sees economy as a challenge, mainly in the choice of methods. “The  
22 challenge is to establish methods, let us say financially. For instance, we have to decide whether to  
23 use pay-back or LCC.” Energy wise it’s also difficult to find standardized calculation methods,  
24 especially for occupant behavior since our building stock has more tenants per square meter than  
25 the Swedish average.  
26  
27  
28  
29  
30

31  
32  
33 In Municipal company B, they include sustainability and state that the main challenge is to find  
34 the right balance between economic investments and sustainability. The company also mentions  
35 the importance of choosing technical solutions that are simple enough to run and maintain. “We  
36 get the best results when we “keep it simple”. Still, we need competent personnel.”  
37  
38  
39  
40

41  
42 The private company did not mention specific challenges but instead stated that the economy is  
43 of no concern as long as the pay-back time of energy efficiency measures does not exceed 7-10  
44 years.  
45  
46  
47  
48

49 **How housing owners prioritize energy efficiency measures in order to secure**  
50 **environmental sustainability**  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 When prioritizing energy efficiency measures, ByggDialog Dalarna suggest that housing owners  
4 owners should work according to the Kyoto pyramid – first of all, creating energy-efficient  
5 buildings by reducing heat loss, mentioning that “One saved kWh is a good kWh!” They also  
6 promote EPC as a method to help housing owners to implement energy efficiency measures. It is  
7 believed that LCA will become more and more important in the future to secure sustainability  
8 and to save natural resources.  
9  
10  
11  
12  
13  
14  
15

16 In Municipal company A, they approach energy efficiency measures from an energy systems  
17 perspective, one reason being that they take the local energy company into consideration. “We  
18 have to consider the energy system boundary and the fact that we are in the same concern as the  
19 local energy company. For instance, we don’t invest in solar panels because then we would  
20 compete in energy production with the energy company.”  
21  
22  
23  
24  
25  
26  
27

28 Municipal company B has set clear goals for energy reduction, and has prioritized reduced  
29 electricity use. “In 2007 we decided to set goals to reduce the heat and electricity demand by 20%  
30 by 2016. We have, since then, focused mostly on lowering the electricity demand because  
31 electricity use has a much higher environmental impact. It seems as if we will accomplish both  
32 these goals. In addition, we have invested in wind power plants and electrical cars in the  
33 company.”  
34  
35  
36  
37  
38  
39  
40  
41

42 In the private company, the priority has been to convert from fossil fuels to other energy carriers  
43 where solar energy is also discussed as an option. Within the company, there is also an ongoing  
44 debate which of district heating or heat pumps is the better choice.  
45  
46  
47  
48

49 **Structural aspects in the building sector and the role of consultants**  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 In Municipal company A, they present an ambition to reduce the need for consultants and  
4 instead build up knowledge within the company. For that reason, they never do EPC. Even so  
5 they  
6  
7

8  
9 “...often have to use consultants and they obviously have their own agenda.”  
10

11  
12 Similar to above, Municipal company B also feel the importance of having enough knowledge  
13 within the company. The company has strict tendering processes and works with turn-key  
14 contracts where clear and precise specifications for the entrepreneurs are of importance. “With  
15 our methods, where we do a lot ourselves, we save time and get offers from more companies in  
16 the tendering process.”  
17  
18  
19  
20  
21  
22

23  
24 In the private company, there is dependence on consultants but they also state a need for  
25 knowledge within the company. “We are dependent on consultants, but we have just recruited  
26 our own energy expert because we need a certain level of expertise to make good decisions.”  
27  
28  
29  
30

### 31 **Methods in project management for making sure important experience is recycled**

32  
33  
34 A systematic approach is crucial, according to the organization ByggDialog Dalarna. They stress  
35 that it is vital to measure and document what goes well and what goes badly. Using certification  
36 systems can be one way to ensure a good structure, to save time and to set requirements for the  
37 functionality and/or performance of energy systems without having in depth understanding.  
38  
39  
40  
41  
42  
43

44 In Municipal company A, it is simply stated that they evaluate and document what they do, and  
45 then hold internal workshops on it.  
46  
47  
48

49 For Municipal company B, statistics are important. To collect statistics, they perform surveys and  
50 collect measurements in buildings during operation. They recycle information and use the same  
51 specifications from one tendering process to the next.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 As for the private company, they use software to monitor the energy consumption of each of  
4 their buildings over time. Occupant behavior is also included. Using this information, they can  
5 evaluate the effect of changes to the buildings and discuss new strategies. When comparing with  
6 other companies, they “...turn to other regional companies, and benchmark according to “The  
7 Dala strategy for Low Energy Buildings” by ByggDialog Dalarna, rather than following national  
8 examples.”  
9  
10  
11  
12  
13  
14  
15

## 16 **5 Discussion**

17  
18  
19 There is a general opinion that the building sector, especially the housing owners, needs  
20 improvement in expertise and knowledge to make good decisions about energy-efficient  
21 refurbishments and to identify appropriate refurbishment packages thus increasing the  
22 refurbishment rate (statement confirmed by the representative from ByggDialog Dalarna: first  
23 question in the interview). The national board of housing, SNBHBP, together with the Swedish  
24 energy agency, addressed the need for a national information center about refurbishment to  
25 increase expertise in housing owners (report ET 2013:22 and Boverket 2015:47).  
26  
27  
28  
29  
30  
31  
32  
33  
34

35  
36 Yet, the housing owners questioned in this study the claim that they have adequate knowledge of  
37 the national energy performance of buildings regulations and goals. The housing owners, on the  
38 other hand, mention other obvious reasons why energy-efficient refurbishment is sometimes  
39 challenging, consequently leading to slow refurbishment rates:  
40  
41  
42  
43  
44

- 45 • Energy efficiency actions need to be wisely chosen to get a balance between social, ecological  
46 and economic sustainability. That is the main challenge of today. The trend goes towards less  
47 ambitious refurbishment projects to secure social sustainability and to avoid increased rent  
48 levels for tenants. More cost-efficient and rational demonstration projects are needed to  
49 inspire and boost the refurbishment rate. “As municipal housing owners we have a  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

responsibility to offer affordable housing for all kinds of people”, replied municipal company A to the first question in the interview.

- Calculated energy performance levels are seldom reached in reality in refurbishment projects. Consequently, the economic benefits of refurbishment are smaller than consultants claim. “There is a distrust of consultants’ work. Therefore, the in-house know-how is extremely important”, claimed the housing owners at the workshops.
- The housing owners even expressed the view that there has been a mismatch between EU directives and national regulations. “Refurbishment is more complex than following the rule of thumb that one kWh saved is one kWh saved”, replied Municipal company B to the first question. “It is most of all important to lower the kWh of electricity use. One needs to have energy system perspective since most multi-family buildings are heated by district heating. It would be better to have national regulations on primary energy use or the carbon dioxide footprint rather than purchased energy”, the same technical manager explained. Some companies claim that the refurbishment rate might increase with new building regulations with clear rules regarding refurbishment based on primary energy use.

The purpose of the study was rather to find out the perceptions of important actors, which could slow the refurbishment rate, than to establish the actual knowledge housing owners have about national building regulations and goals. There are several good reasons for this and the main reason is obviously that managers and other important actors make their decisions on what they perceive as knowledge and not on what is objectively acknowledged as this [54]. The general results (and Figure 1), can be interpreted as that housing owners have not felt very restricted nor motivated by the former Swedish building regulations and energy goals in refurbishment projects, even if they have knowledge about these aspects. Apart from the points mentioned above, the reasons could be unclear regulations regarding refurbishment, and that regulations not followed up by the authorities. Instead, the housing owners tend to assess the actions of their colleagues to

1  
2  
3 find inspiration for energy-efficient refurbishments. The major motivation is most probably  
4 financial savings, but the companies also consider the other sustainability aspects. Small  
5 companies learn from the larger local companies and regional forums such as ByggDialog  
6 Dalarna, rather than acquiring information from authorities or “Renoveringscentrum” at a  
7 national level. The data gathered in the study indicates that the knowledge level about energy  
8 efficiency work is somewhat higher among large municipal housing owners than in the small  
9 private companies.  
10  
11  
12  
13  
14  
15  
16  
17

18 In order to spread new scientific information or guidelines, it is, therefore, crucial to inspire  
19 representatives from the large housing owners to take part in events where important  
20 information is given and encourage them to take back the message to the regional level. SABO  
21 and BEBO meetings were said to be of special importance to the larger companies, which can  
22 often afford to participate in these events with their own energy experts. The sooner the large  
23 housing owners take back and demonstrate new procedures and new technology, the faster they  
24 are adopted by other housing owners in the sector.  
25  
26  
27  
28  
29  
30  
31  
32  
33

34 A SNBHBP report from 2016 concluded that the main challenges housing owners face are  
35 related to high expenses in the building sector [12]. So far there have probably been spread  
36 information about too few demonstration projects showing standardized and rational  
37 refurbishment of multi-family housing which have been really successful in all aspects ranging  
38 from economy to energy performance and social aspects. Many have been too costly, resulting in  
39 increased rent for tenants. Others have not met the expected energy performance, or not been  
40 followed up at all.

51 The main conclusion from this study is that an information center is not worth much without  
52 good demonstration projects to learn and report from. Many companies will probably continue  
53 to hesitate until refurbishment packages have been implemented, the whole refurbishment  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 process has been followed up and demonstrated and documented using a holistic approach.

4 Ongoing national demonstration projects, or “Living Labs”, such as “Gentle Energy-Efficient  
5 refurbishment”, where the building energy performance and social aspect are followed through  
6 the whole renovation process and for a considerable period after the building has been finalized,  
7 are promising as relevant and useful inspiration for many housing owners. Monitoring the energy  
8 performance of renovated buildings is especially important to tackle the gap between predicted  
9 and actual energy performance.

19 In particular, energy occupant behavior in buildings is a key issue for building design  
20 optimization, energy diagnosis, performance evaluation, and building energy modeling due to its  
21 significant impact on real energy use and indoor environmental quality in buildings. The behavior  
22 includes adjusting thermostats for comfort, switching lights on/off, opening/closing windows,  
23 pulling up/down window blinds, and moving between spaces. However, the influence of  
24 occupant behavior is usually under-recognized or over-simplified in design, construction,  
25 operation, and retrofit of buildings, leading to great differences in practical building energy use  
26 compared to simulation results. Occupant behavior is complex, stochastic and multi-disciplinary.  
27 Thus, having detailed understanding of occupant behavior and being able to quantify its impact  
28 on use of building technologies and energy performance of buildings is crucial to the renovation  
29 of energy-efficient buildings. Consultants may also lack this in depth understanding needed or  
30 may have to communicate their results in a different way.

45 It is very important to have expertise on energy efficiency and refurbishment within individual  
46 companies, according to almost all the housing owners questioned. More than 90 % express the  
47 view that it is vital to recycle knowledge from one refurbishment project to the next (see Table  
48 1). Most of them do not fully trust consultants and/or do not believe in energy performance  
49 contracting (EPC) services because they know their own buildings better than anybody else, and  
50 therefore think it is risky to leave the refurbishment process to an external partner.

1  
2  
3 Still, more than half of the housing owners participating in this study expressed the view that  
4 refurbishment projects seldom have clear goals, proper project management to reach the goals,  
5 and verification of fulfillment afterwards (Table 1). It seems as if the sector still seeks  
6 standardized refurbishment strategies and tools to secure sustainable and efficient refurbishment  
7 processes. The answers and discussion at the workshops point to the conclusion that, nowadays,  
8 the housing owners lack the time to work through all necessary stages of a refurbishment process  
9 themselves. Even if they would like to use the available planning tools, and spread knowledge in  
10 their own organization, they do not do so (Table 1). Instead, they depend on consultants taking  
11 measures. It seems as if better defined methods/tools adapted for refurbishment could be of  
12 great value in the coming years. These would improve interaction between those with in-house  
13 knowledge and consultants, would save time and improve quality in a fast moving building sector.  
14 Building certification tools such as BREEAM, LEED, WELL or “Miljöbyggnad” could fulfill this  
15 function, or “Renobuild”. Although these tools have their own characteristics and may be applied  
16 in different scenarios, it is usually very hard in practice for housing owners to make a decision on  
17 which tool should be chosen, due to the lack of the integrated comparison among these rating  
18 systems. Further case studies, knowledge delivery and tool training must be conducted to tackle  
19 this practical challenge.

41 The energy “performance gap” is also an issue that, at least partly, is related to the tools used  
42 when planning a refurbishment. Most of the tools available use standardized values for many  
43 parameters, which can be a contributing factor to the calculated energy performance deviating  
44 from the real measured performance. This is discussed in [55], where the difference between  
45 optimal but realistic conditions of use and standard values used in the simulation process is one  
46 of two main issues, the second issue being the difference between optimal and actual conditions  
47 of use. The authors [55] question if it is even sensible to use standard calculation methods to  
48 estimate real energy savings at building level or use them to design retrofit strategies.

1  
2  
3 The interaction between housing owners and local energy companies was also touched upon in  
4 this study. In general, the housing owners do not believe dialogue with the energy companies is  
5 crucial when choosing energy efficiency measures (even if their buildings have district heating).  
6  
7 The large companies, however, stress the importance of having an energy system perspective in  
8 refurbishment projects (as reported in the interviews). The energy companies themselves wish for  
9 a closer dialog with the housing owners (Table 1). As the energy performance of more and more  
10 existing buildings is improved, smart energy system solutions are needed as this affects the whole  
11 heat market and the premises for energy production.  
12

19  
20 Financial incitements were proposed as a part of the strategies in report ET 2013:22 and  
21 Boverket 2015:47 by SNBHP and the Swedish Energy Agency. In the present study, the  
22 housing owners did not stress economic aspects very much, even if economy is the main bottle  
23 neck for refurbishment. They did not make suggestions for new incitements, as loans given today  
24 already have low interest rates.  
25  
26  
27  
28  
29  
30

31  
32 As regards the general validity of the results, these should primarily be considered valid for the  
33 population and the selection of subjects from which the study is based. For attributions to other  
34 populations, these should be done with caution. Based on the selection and principles for data  
35 collection that has been made, it is clearly reasonable, though, to assume that for the purpose of  
36 this study significant data and information have been identified as basis for the analysis.  
37  
38 Regarding the reliability of data and results, it is of importance that the measures were taken to  
39 assure that respondents were well aware of the implications of the questions. With regard to the  
40 qualitative survey, reliability has been sought by choosing subjects carefully and allowing them to  
41 freely and adequately express their views based on the general open themes presented to them.

## 51 52 **Conclusions** 53 54 55 56 57 58 59 60

1  
2  
3 Improving the energy performance of existing buildings is crucial for reaching both EU and  
4 national climate and energy targets, moving towards a more sustainable energy system. SNBHBP  
5 and the Swedish Energy Agency have worked on a national Swedish strategy to increase the rate  
6 of energy-efficient refurbishment (ET 2013:22 and Boverket 2015:47). This strategy comprises a  
7 national information center to increase the expertise in the building sector, especially among  
8 housing owners, as well as financial incitements.  
9  
10  
11  
12  
13  
14  
15

16 In this study, housing owners themselves express the view that they have sufficient knowledge of  
17 the national regulations and goals. Despite their supposed knowledge of the national ambitions to  
18 improve the energy performance of buildings, and the current economic situation with beneficial  
19 loans, the refurbishment rate still remains low. The housing owners explain that they are waiting  
20 for proof that all sustainability goals can be reached in refurbishment projects in reality. Too few  
21 projects have fulfilled ambitions in all categories: economically, socially, and energy-wise.  
22  
23  
24  
25  
26  
27  
28

29 Probably, the government should stimulate to have more projects demonstrating rational energy-  
30 efficient refurbishment with a holistic approach taking economic, ecological and social  
31 innovations into account. These demonstrations should include monitoring of energy  
32 performance for a few years after the building have been finalized. This way it will be clear which  
33 projects/methods have been successful when it comes to energy performance predictions and  
34 interaction between housing owners and consultants.  
35  
36  
37  
38  
39  
40  
41  
42

43 The new national information center about refurbishment of buildings may be crucial to spread  
44 information nationally, especially to reach energy experts or technical managers of the large  
45 housing owners. Even if the housing owners have a perceived understanding about energy  
46 efficient refurbishment, the lack of knowledge may still be an issue. Once the large housing  
47 owners acquire an understanding of total concept methods for refurbishment, and bring back  
48 their knowledge, the smaller regional companies are likely to follow and thus increase the  
49 refurbishment rate.

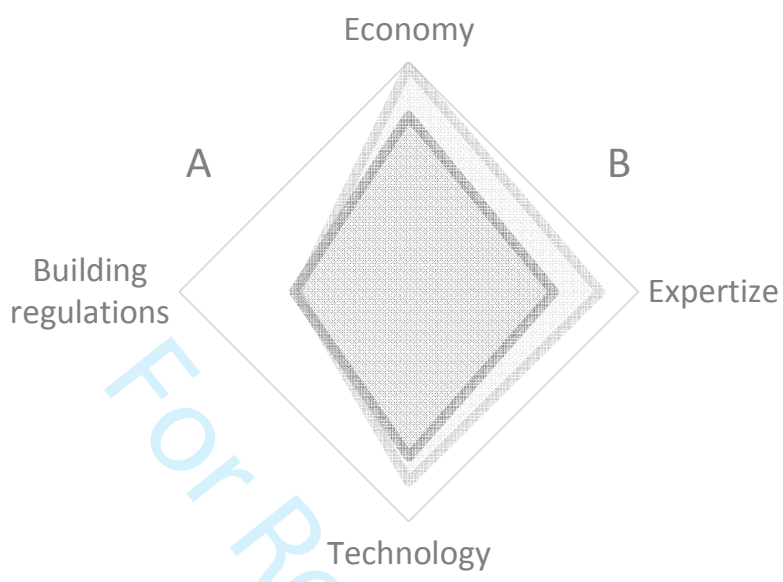

Figure 1. Challenging factors in energy-efficient refurbishment for real estate companies. Response from housing owners are denoted A and energy companies denoted B. Aspects considered as great limitations are indicated by points far from origo.

Table 1. Questions about energy-efficient refurbishment and corresponding answers. Housing owners are denoted A and energy companies denoted B.

		Very much	Considerable	To some extent	No	No opinion
Do housing owners have sufficient knowledge about the national building regulations and future energy targets?	A	27%	47%	20%	7%	0%
	B					
Can tools like Sveby, Bygga E and building certification systems such as BREEAM, LEED, WELL or "Miljöbyggnad" be useful in order to choose refurbishment measures?	A	67%	27%	0%	0%	7%
	B	39%	23%	15%	15%	8%
How dependent are housing owners on consultants in energy efficiency work?	A	29%	64%	7%	0%	0%
	B	61%	31%	0%	0%	8%
		Vital	Important	Slight importance	Not important	No opinion
How important is it to consider social sustainability in refurbishment projects?	A	13%	53%	33%	0%	0%
	B	23%	31%	15%	23%	8%
How important is it to recycle knowledge from one refurbishment project to the next?	A	93%	7%	0%	0%	0%
	B					
How important is dialogue with the energy companies when choosing energy-efficiency measures for buildings?	A	0%	27%	47%	27%	0%
	B	23%	38%	8%	15%	15%
		Always	Frequently	Seldom	Never	No opinion
Do refurbishment projects in Sweden have clear goals, proper project management to reach the goals and verification of fulfillment afterwards?	A	7%	20%	53%	0%	20%
	B
